

4. Exogenetic Processes Part –II

Std 9th

Sub – Geography

Q 1. Rewrite the correct statement :

(1) The temperature range helps the wind in its work.

Ans. Right

(2) River's work is more prominent than other agents of erosion in desert regions.

Ans. Wrong - work of wind is more prominent in desert region than other agents of erosion.

(3) The work of groundwater is effective in the area with soft rocks.

Ans. Right

(4) The work of wind is not limited like river, glacier or the sea waves and takes place everywhere.

Ans. Right

Q 2. Correct and rewrite the incorrect statements :

(1) The ice on the lateral side of the glacier moves faster than the ice at the base.

Ans. Wrong - The ice on the base of the glacier moves faster than ice on the lateral side.

(2) The depositional work by rivers happens because of gentle slope, reduced speed and transported sediments.

Ans. Right

(3) A river flows at a faster speed than the glacier.

Ans. Right

(4) The speed of the glacier is more on both the banks than in the middle.

Ans. Right

Q 3. Identify the wrong pair

(1) Deposition - V-shaped valley

Ans. Wrong : Erosion - V-shaped valley

(2) Transport - Ripple Marks

Ans. Right

(3) Erosion - Mushroom Rocks

Ans. Right

Q 4. Identify and name the landforms in the following diagrams :

V-Shaped valley

Gorge

Delta

Q 5. Complete the following table by classifying the landforms according to their agents of erosion.

Rivers	Wind	Glacier	Sea Waves	Groundwater
waterfall, delta, pothole	barchans, mushroom rock,	cirque, arête, moraine	Beach, lagoons	Sinkholes, pillars

Q 6. Answer the following questions in brief.

(1) List the landforms that are a result of the erosional work of the rivers.

Ans. 1. The rivers originate at a much higher altitude from the sea level.

2. Here, the river flows at a great speed and therefore, its power to erode is great.

3. The riverbed and the river banks get eroded because of the fast flow of water, sand particles, pebbles. etc. and the various tributaries joining the main river.

4. All these lead to the formation of gorges (canyons), V-shaped valleys and waterfalls.

(2) Which agent is responsible for formation of stalactites and stalagmites and where are they formed?

Ans. 1. The work of groundwater is responsible for the formation of stalactites and stalagmites.

2. In areas of limestone, the alkaline water flows through the roof of the limestone.
3. When this water evaporates, minerals deposited at the bottom and at the top of the limestone caves.
4. This leads to the formation of stalactites and stalagmites caves.

(3) List the landforms that are produced by the depositional work of the sea waves .

Ans. 1. The eroded materials accumulate at the sea bed. Because of tides, they keep on moving towards the coast and away from the coast.

2. They become fine because of attrition and hitting each other. Deposition of such materials occurs at the places where the effect of waves is less.

3. Landforms like beaches, sand bars, lagoons are formed due to depositional work of the sea waves.

(4) Name the types of moraines.

Ans. The glaciers carry sediments with them. These sediments are called moraines. Depending on the location of the deposits, moraines can be divided into four types ground moraines, lateral moraines, medial moraines and terminal moraines

1. The material deposited at the base of a glacier is called ground moraine.

2. The material deposited along the banks of glacier is called lateral moraine.

3. After the confluence of two glaciers, the moraine deposited in the central part of the glaciers known as medial moraine. It is formed out of the side moraine of the inner banks of the two glaciers.

4. At the end where the glacier turns into a stream, huge quantity of moraine is deposited. The stream of water is unable to carry the moraine further. As the deposited moraine is at the terminal part of a glacier, it is called the terminal moraine.
